

# **Experimental Plan for Cold Fusion Using the Latest 2-D Materials**

Realizing a new energy source to pioneer the future of humanity  
through the combination of advanced materials!

**Nano Fusion Design**

nanofusion.design

# About Nano Fusion Design

- Founded by Ryoji Furui in November 2023 to realize nuclear fusion using graphene materials. <sup>(1)</sup>
- Excess heat has not been confirmed with graphene material and hydrogen under pressures below 10 atmospheres. <sup>(2)</sup>
- Confirmed excess heat with terahertz pulses. <sup>(3)</sup>

- Experiments are planned using terahertz-emitting graphene <sup>(4)</sup> and borophane (mass hydrogen density 8.5 wt%, volumetric hydrogen density 133.4 kg/m<sup>3</sup>) as hydrogen carriers.

# What is Cold Fusion?

- A dream energy source that has continued to be researched and developed since its discovery about 30 years ago.
- Fusion reactions have been confirmed, but are still developing as a highly efficient and quantifiable practical energy source.
- Unlike fusion that heats impurity-free hydrogen fuel to 1 billion °C, cold fusion achieves fusion with hydrogen absorbed into metals like nickel at temperatures below 1000 °C.

- Solving various problems and realizing dream energy with the latest 2-D materials!

# About Graphene and Borophane

## Graphene

- Hexagonal carbon lattice, melting point 3000°C
- Fermi velocity 6000 km/s (copper is 1600 km/s)  
⇒ Terahertz oscillation
- Medium to convert hydrogen to ultralow-momentum neutrons via electron capture <sup>(5)</sup>

## Borophane (Borohydride Sheet)

- First produced in Japan in 2017 <sup>(6)</sup>
- Composed of hydrogen and boron in a 1:1 ratio, releases hydrogen when exposed to ultraviolet light or heated above 200°C
- Fusion fuel, hydrogen and boron fuse to form helium

# Fusion Process with Electron Capture

1. Hydrogen desorbs from borophane heated above 200 °C.

2. Hydrogen collides with fast electrons on graphene and converts to neutrons.

3. Neutrons fuse with boron and convert to helium, releasing nuclear energy. <sup>(7)</sup>

# Experimental Procedures

1. Encapsulate powdered graphene and borophane in a pressure-resistant container of 1–100 mL, with a vacuum level of  $1 \times 10^{-3}$  [torr] to several hundred MPa, and perform vacuum evacuation. (During the initial stages of the experiment, the container performance can be low-spec, gradually increasing in stages)
2. Heat the container's outer wall to several hundred °C for several hours with an electric heating wire wrapped around.
3. Confirm excess heat on the outer wall (heat generation due to fusion).
4. After stopping heating, cool to room temperature.
5. Collect and conduct mass spectrometry analysis on the gas inside the container.

# Schematic Diagram of the Experimental Setup

# Safety Management in Experiments

- Handling High-Temperature, High-Pressure Gas
  - In the experiment, high-pressure hydrogen gas is generated at temperatures of several hundred °C from solid fuel. If it leaks outside the container, there is a risk of hydrogen explosion.
  - The experiment should be conducted with equipment and safety measures in place to anticipate such risks, in accordance with relevant laws.
  - The possibility of excess heat generation due to nuclear reactions should be also taken into consideration.
- Generation of Radioactive Substances
  - High-pressure gas and residual powder generated during the experiment may contain trace amounts of tritium and the radioactive carbon isotope C14.
  - In the initial stages of the experiment, the residual amount is expected to be below regulatory limits <sup>(8)</sup>, but the experiment should be conducted under a management system that includes mass spectrometry of waste.

# Development after Proof-of-Concept Experiment

1. Optimization of the Mixing Ratio and Powder Shape of Graphene and Borophane
  - The optimal mixing ratio of graphene and borophane, as well as the powder shape and furnace temperature, will be explored through experiments and computer simulations.
2. Development of Fuel Rods for High Load and Long-term Operation
  - Utilize the new nuclear fuel rod development facility <sup>(9)</sup> to be established at Tohoku University in March of this year to develop fuel rods that can withstand high loads and long-term operation.
3. Introduction to Small Modular Reactors (SMR) and Others
  - Introduce fuel rods that can be operated as heat sources into reactors optimized for their output, and develop complete packages such as boilers or SMRs aimed at power generation.

# Development Funding and Intellectual Property Rights

- Development Funding
  - Nano Fusion Design needs to address the lack of specialized personnel, materials, and funds in the proposed development plan by building a cooperative structure to meet these needs.
- Handling of Intellectual Property Rights
  - The potential intellectual property rights could have widespread public dissemination and utilization as a new energy source.
  - While taking into consideration the development cost of the rights, it is also necessary to exercise the rights in a way that contributes to technological advancement and energy cost reduction.
